

openHPSDR Ethernet Protocol

V2.1

©November 2015 Phil Harman VK6PH

Revisions

| Rev | Date | Changes | By |
|-----|--------------|---|------------------------|
| 1.0 | 20 June 2015 | First release | VK6PH |
| 1.1 | 27 June 2015 | Changed Hermes Lite reference number from 5 to 6. Added DSP clock frequency and number of receivers implemented to Discovery reply. Enable either receiver and transmitter frequency or phase word to be sent to hardware. Added memory mapped registers. | VK6PH KF7O |
| 1.2 | 1 July 2015 | Added version of Protocol implemented and frequency or phase word required to Discovery reply packet. | VK6PH |
| 1.3 | 2 July 2015 | Corrected network format to be Network Byte Order, or Big-Endian. | N2ADR |
| 1.4 | 1 Aug 2015 | Added Wideband packets per frame to General Packet | VK6PH |
| 1.5 | 27 Aug 2015 | Corrected General Packet source and destination ports. Corrected Microphone and Wideband data packets source port. Removed default Wideband data rate, added default samples per frame for ANAN-10E. Removed blank page 15. Changed discovery hardware identification numbers to allow ANAN-10E to be identified. Added full hardware description option for Discovery reply. Added hardware time out should communications with host be lost. | VK6PH G4ELI |
| 1.6 | 6 Sept 2015 | Added 10MHz reference PLL locked to High Priority packet | G4ELI |
| 1.7 | 14 Sept 2015 | Added data format where 2's complement used. Added calibration information e.g. max I&Q value for -20dBm input. Corrected Envelope PWM_min and max settings, corrected byte 38 in General Packet to SDR, Corrected DDck,0 in Figure 3. | VK6PH IW0HDV |
| 1.8 | 16 Oct 2015 | Added Discovery reply for ANAN-100E, clarified where DSP clock frequency is obtained. | VK6PH |
| 1.9 | 24 Oct 2015 | Various typographical errors corrected. Clarified number of samples per Ethernet packet for Audio and I&Q data. Added Appendix C – block diagram of Alex filters. | G4ELI, VK6PH |
| 2.0 | 28 Oct 2015 | Clarified Open Collector drive. Added NOTE1 and 2 on page 3 relating to PureSignal operation, Tx I&Q data and Tx architecture. Added number of general purpose ADCs support to Appendix A. Expanded Alex filter operation in Appendix C. Added note on Page 19 relating to synchronous and multiplexed receiver restrictions. | G4ELI, VK6PH, KC9XG |

| | | | |
|-----|------------|---|---------------------|
| 2.1 | 9 Nov 2015 | Added additional Alex filter descriptions in Appendix D. Increased support for Alex filters from 4 to 8. NOTE: Open Collector register in High Priority packet has moved due to this. Added support for XLM format Discovery reply. Clarified PA enable and Envelope Tracking bits. Added note that ANAN-10E only has 31dB attenuator. Corrected number of I&Q samples in Receiver packet. Corrected number of bytes in receiver packet. Added conversion constants for supply volts, exciter, Forward and Reverse power to Appendix A. | VK6PH, KC9XG, G4ELI |
| | | | |
| | | | |

Acknowledgements

My thanks to Jeremy, NH6Z, for providing the initial suggestions regarding a possible protocol and for the suggested document format.

Thanks also to Alex, VE3NEA, for the original suggestion of using UDP ports to send and receive data from.

Special thanks to Scotty, WA2DFI, for his detail analysis of the early drafts of this protocol and numerous significant contributions.

The follow have provided input and review of the protocol during its development:

Warren - NR0V, Doug - W5WC, Joe - K5SO, Chen - W7AY, George - K9TRV, Leif – SM5BSZ, Simon - G4ELI, Vasiliy - K3IT, Tom - N5EG, Edson - PY2SDR, Dave - KV0S, Alex - VE3NEA, John – G0ORX, Francis - ON5RF, Alberto – I2PHD, David - WA8YWQ, Roger – W3SZ, Bob - G3UKB, Steve-K7FO.

Thanks to William, KC9XG, for preparing the Alex filter block diagrams.

Thanks also to those contributors who wish to remain anonymous.

Purpose

This specification describes the protocol used to communicate with current and future openHPSR hardware. Its intended audience is hardware and software developers who wish to develop, or modify, hardware and software to use this architecture and protocol.

Architecture

The basic architecture is built on the concept of using UDP ports to send and receive signals and Command & Control data.

Some configuration settings will change infrequently and can be applied to all receivers and transmitters. These 'General' settings need only be sent when the SDR hardware is first turned on or when a setting changes during operation.

Settings that need to change more frequently are sent to control registers associated with receivers or transmitters.

Settings that require near real-time responses are sent as priority packets to specific UDP ports.

Where possible the protocol does not restrict the number of configurable resources. The number of fully independent receivers, associated with a particular analogue to digital converter (ADC), can be configured using the General settings. Similarly, the number of receivers or transmitters that may be combined synchronously or multiplexed is configurable.

The basic architecture for UDP data from the Host (i.e. PC, Tablet etc) is shown in Figure 1. The UDP ports here configure General Registers (where data changes infrequently after initialisation), Transmitter and Receiver Specific Registers and High Priority Registers (where, for example, register settings change between receive and transmit).

Figure 2 illustrates the architecture for UDP data from the SDR hardware to the Host. The ports here include the Microphone data and both wide and narrow band receiver data ports.

In both diagrams some UDP ports are predetermined. Others are set by the user and/or depending on the actual number of ADCs and DACs available on the specific SDR hardware and the number of synchronous and non-synchronous (i.e. multiplexed) receivers and transmitters the user wishes to configure.

Figure 3 illustrates how multiple receivers can be configured on a specific ADC. It also shows how a specific receiver can be configured to be synchronous or multiplexed with other receivers configured on other ADCs.

In general the input of a specific Digital Down Converter (DDC) can be fed from a selected ADC or, for PureSignal requirements, from the data being sent to a specific DAC. Each DDC can operate independently from all others i.e. its sampling rate is set independently.

Where no synchronous or multiplexed receivers are selected then the output of the DDC directly feeds a FIFO and subsequently, using its designated port, the Ethernet PHY.

Where synchronous or multiplexed receivers are selected then the data from these additional receivers are sequentially passed to the FIFO associated with the base receiver DDC. All synchronous or multiplexed receivers must operate at the same sampling rate.

Synchronous receivers are phase coherent whilst multiplexed receivers can be set to different frequencies.

The maximum number of synchronous receivers that can be selected per base receiver is equal to the number of ADCs. The maximum number of multiplexed receivers per base receiver is equal to the number of receivers implemented.

The DDC follows the conventional architecture of CORDIC, CIC filters and sinc compensating FIR filter.

Figure 4 illustrates how multiple transmitters can be configured in either synchronous or multiplexed modes. Presently, no openHPSDR SDR hardware is able to support more than one DAC. In which case data from the FIFO connect to port 1029 (default) is connected directly to the Digital Up Converter (DUC) and the selection of synchronous or multiplexed data is not supported.

The transmitter uses a DUC configured as a 5 stage CIC filter and CORDIC. Note that the Host I&Q data (24 bit I&Q data at 192ksps) directly feeds the CIC filter. In which case the transmitted signal will be -1dB at +/- 22kHz. For most modes this is acceptable but should wider bandwidths be required the designer may wish to include a sinc compensation filter in the Host software.

In order to overcome any potential latency issues between the Host and SDR Hardware, RF and sidetone generation for CW is done in the SDR Hardware. This includes applying a raised cosine profile to the leading and trailing edges of the CW RF and sidetone waveforms. An Iambic Keyer is also implemented and operates in Straight, simulated Bug and Iambic A or B.

Variable frequency and amplitude sidetone is also generated in the SDR Hardware.

Time stamping of receiver I & Q packets is in accordance with the VITA-49 specification for Fractional-seconds Timestamps.

For the current hardware implementation an arbitrary limit of 80 receivers and 8 ADCs has been applied. These limits will be removed as hardware that is capable of exceeding these settings becomes available.

Compared with the previous openHPSDR Ethernet/USB protocol, numerous new features and facilities have been added. However, we should bear in mind the 'Second-system effect' - see

http://en.wikipedia.org/wiki/Second-system_effect

Detailed operation

Consider a network made up of multiple SDRs and multiple Hosts (e.g. PCs). Each SDR on the network has a unique IP address, and listens on fixed port 1024 for Discovery packets.

The following scenario outlines how SDRs and Hosts interact within a given network segment. It is important that multiple SDRs and multiple Hosts each running multiple applications be able to interact on one segment. Note that the term “SDR” applies to a single network connection (IP address); there may be many hardware ports associated with each single IP address.

To establish communication, one network Host will broadcast a Discovery to address <255.255.255.255:1024> from its own IP address and a source port number. In this example, assume it is from <192.168.1.10:8000>.

Every device listening on port 1024 will respond to this broadcast with a response to the Hosts IP address and source port with its IP address and port number. In this example, the SDR responds to <192.168.1.10:8000> from its own fixed address of <192.168.1.30:1024>. Now a command/response channel has been established between the SDR and the Host. This channel will be used for all SDR-to-Host and Host-to-SDR communications until one or more other streams are established.

Once a channel has been established then the General Registers and Receiver and Transmitter Specific Registers should be set up. A High Priority packet should then be sent with the ‘run’ bit set in order to start data from the Hardware.

In order to recover from a network interruption, a Command & Control packet (i.e. any C&C packet) must be sent from the host to the hardware at least every second (every 100 mS is recommended). Should a C&C packet not be received, and the hardware is in the RUN state, then the hardware will switch out of the RUN state into standby. The session can be re-started either by sending a High Priority Packet with the RUN bit set, if the same network session is still active, or a Discovery exchange followed by re-initiation of all C&C settings and thence a High Priority Packet with the RUN bit set.

The format of the Ethernet packets is generally consistent in that they all commence with a 32 bit sequence number. This enables the Host and Hardware to determine if packets have been lost.

In general, configuration data that is typically required by all SDR hardware is sent at the head of a packet. Settings that are specific to openHPSDR hardware are sent at the end of a packet. This leaves room in the middle of the packet for additional register settings to be included in the future without disturbing existing settings.

NOTE1: The protocol provides for any ADC to be used for PureSignal RF and DAC feedback. However, due to FPGA size limitations and timing requirements, for all current implementations RF feedback will be via Rx0 and DAC feedback via Rx1.

NOTE2: The protocol enables a variable transmitter I&Q sample width and sample rate. For all current openHPSDR implementations the sample width is set to 24 bits and sampling rate fixed at 192 ksps.

openHPSDR Host to Hardware Protocol

The Host will communicate with the Hardware using standard UDP protocol. Byte order shall be MSB first (Network Byte Order, or Big-Endian) and all values are interpreted as unsigned integers unless otherwise noted.

IP and UDP headers are as per UDP/IP standards.

Key:

| |
|---------------------------|
| IP Header (24 bytes) |
| UDP Header (8 bytes) |
| UDP Data (variable bytes) |

| <div>Bits</div> <div>Bytes</div> | 0-7 | 8-15 | 16-23 | 24-31 | 32- 39 | 40-47 | 48-55 | 56-63 |
|----------------------------------|------------------------|-----------------|------------------|-------|-------------------|-------|-----------------------|-------|
| 0 | Version/IHL | Type of Service | Total Length | | Identification | | Flags/Fragment Offset | |
| 8 | TTL | Protocol | Header Checksum | | Source IP Address | | | |
| 16 | Destination IP Address | | | | IP Options | | | Pad |
| 24 | Source Port | | Destination Port | | UDP Length | | UDP Checksum | |
| 32... 1443 | UDP Data | | | | | | | |

Future diagrams will only show the UDP Data with a starting byte reference of zero.

DISCOVERY PACKET

A Discovery packet is broadcast from a Host in order to determine what SDRs are present on the network, and if so, how many. The format is as follows:

| | Discovery - PC to Hardware | |
|-------|----------------------------|---------------------|
| Byte | Broadcast to Port 1024 | Notes |
| | | |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | 0x02 | Command - Discovery |
| 5 | | Zero |
| 6 | | Zero |
| 7 | | Zero |
| 8 | | Zero |
| | | |
| 59 | | Zero |

Destination Address

This will be Ethernet address 255.255.255.255.

Destination Port

This will be 1024.

Sequence Number

A 4-byte integer set to 0x00000000.

The hardware will respond with the relevant Command Reply Packet.

ERASE PACKET

An Erase packet is sent from a Host in order to erase the EEPROM on the hardware prior to programming it. The format is as follows:

| | Erase Command - PC to Hardware | |
|------|---|-----------------|
| Byte | To IP Address of Hardware and Port 1024 | Notes |
| | | |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | 0x04 | Command - Erase |
| 5 | Zero | |
| 6 | Zero | |
| 7 | Zero | |
| 8 | Zero | |
| ... | | |
| 59 | Zero | |

Destination Address

This will be the Ethernet address assigned to the hardware.

Destination Port

This will be 1024.

Sequence Number

A 4-byte integer set to 0x00000000.

The hardware will respond with a Command Reply Packet confirming receipt of the Erase command and a subsequent reply when the erase has completed.

NOTE: Larger EEPROMS can take up to 15 seconds to erase. The Host program should include a timer such that if a reply has not been received within this time the user should be prompted to re-try.

PROGRAM PACKET

A Program packet is sent from a Host in order to program the EEPROM on the hardware. The format is as follows:

| | Program Command - PC to Hardware | |
|------|---|-------------------|
| Byte | To IP Address of Hardware and Port 1024 | Notes |
| | | |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | 0x05 | Command - Program |
| 5 | # of blocks [31:24] | |
| 6 | # of blocks [23:16] | |
| 7 | # of blocks [15:8] | |
| 8 | # of blocks [7:0] | |
| 9 | Program data 0 | |
| 10 | Program data 1 | |
| 11 | Program data 2 | |
| 12 | Program data 3 | |
| 13 | Program data 4 | |
| 14 | Program data 5 | |
| 15 | Program data 6 | |
| | | |
| 264 | Program data 255 | |

Destination Address

This will be the Ethernet address assigned to the hardware.

Destination Port

This will be 1024.

Sequence Number

A 4-byte unsigned integer representing a sequence of packets from this port. The sequence starts at 0x00000000, increments for each new packet, and rolls over after exceeding 0xFFFFFFFF.

Each port decoder keeps a separate sequence count such that the hardware can determine if a decoder is missing samples in its stream. The sequence number is set to zero when initiating a Programming sequence.

Number of Blocks

A 4 byte integer that indicates the total number of 256 byte blocks that will be sent from the Host to the SDR hardware.

The hardware will respond with a Command Reply Packet that requests the next block of 256 bytes be sent.

NOTE: Should the Sequence Number in the Command Reply Packet not be consistent with the sent Sequence Number then the Program process should be aborted and the user given the option to restart. An affirmative response should initiate an Erase sequence followed by a Program sequence.

SET IP ADDRESS PACKET

A Set IP Address packet is sent from a Host in order to set the IP address of the hardware. Prior to setting an IP address a Discovery Packet should be sent and the MAC address of the hardware that's IP address is to be updated recorded.

The format is as follows:

| Set IP Address - PC to Hardware | | |
|---------------------------------|------------------------|--------------------------|
| Byte | Broadcast to Port 1024 | Notes |
| | | |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | 0x03 | Command - Set IP Address |
| 5 | ToMAC | MSB |
| 6 | ToMAC | |
| 7 | ToMAC | |
| 8 | ToMAC | |
| 9 | ToMAC | |
| 10 | ToMAC | LSB |
| 11 | AssignIP | MSB |
| 12 | AssignIP | |
| 13 | AssignIP | |
| 14 | AssignIP | LSB |
| 15 | Zero | |
| 16 | Zero | |
| 17 | Zero | |
| 18 | Zero | |
| | | |
| 59 | Zero | |

Destination Address

This will be Ethernet address 255.255.255.255.

Destination Port

This will be 1024.

Sequence Number

A 4-byte integer set to 0x00000000.

MAC Address

A 6-byte value that contains the MAC address of the hardware that's IP address requires to be set.

IP Address

A 4-byte value that contains the IP address that is required to be set in the hardware's EEPROM. This may be increased in the future to enable IPv6 addressing. Setting the IP address to 0.0.0.0 will force the hardware to use DHCP addressing.

NOTE: After the IP address has been saved in EEPROM, which will take a few seconds, the successful setting of the IP address can be verified by sending a Discovery Command. The reply from the hardware will include the new IP address.

GENERAL PACKET TO SDR

The General packet contains data that sets infrequently changed settings of the transceiver subsystems. This data is sent when the UDP data changes and, optionally, periodically.

A General Packet should be sent following a successful Discovery exchange.

The format is as follows:

| | Control Elements - PC to Hardware | |
|------|---|---|
| Byte | To IP Address of Hardware and Port 1024 | Notes |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | 0x00 | Command |
| 5 | Rx Specific port [15:8] | Default Port # 1025 |
| 6 | Rx Specific port [7:0] | |
| 7 | Tx Specific port [15:8] | Default Port # 1026 |
| 8 | Tx Specific port [7:0] | |
| 9 | High Priority from PC port [15:8] | Default Port # 1027 |
| 10 | High Priority from PC port [7:0] | |
| 11 | High Priority to PC port [15:8] | Default Port # 1025 |
| 12 | High Priority to PC port [7:0] | |
| 13 | Receiver Audio port [15:8] | Default Port # 1028 |
| 14 | Receiver Audio port [7:0] | |
| 15 | Tx0 I&Q port [15:8] | Base Port (Default Port # 1029) |
| 16 | Tx0 I&Q port [7:0] | |
| 17 | Rx0 port [15:8] | Base Port (Default Port # 1035), Rx1 = Base Port # + 1....Rx79 = Base Port # + 79 |
| 18 | Rx0 port [7:0] | |
| 19 | Mic samples port [15:8] | Default Port # 1026 |
| 20 | Mic samples port [7:0] | |
| 21 | Wideband ADC0 port [15:8] | Base Port (Default Port # 1027), ADC1 = Base Port # + 1....ADC7 = Base Port # + 7 |
| 22 | Wideband ADC0 port [7:0] | |
| 23 | Wideband Enable [7:0] | WB0 = [0], WB1 = 1.....WB7 = [7] |
| 24 | Wideband Samples per packet [15:8] | Default 512 |
| 25 | Wideband Samples per packet [7:0] | |
| 26 | Wideband sample size | Default 16 bits |
| 27 | Wideband update rate | 0 to 255mS per frame, default 20ms per frame |
| 28 | Wideband packets per frame | Default to 32 (i.e. 16k by 16 bit samples per frame) |
| 29 | Memory mapped from PC port [15:8] | Default Port # xxxx |
| 30 | Memory mapped from PC port [7:0] | |

| | | |
|----|--|--|
| 31 | Memory mapped to PC port [15:8] | Default Port # xxxx |
| 32 | Memory mapped to PC port [7:0] | |
| 33 | Envelope PWM_min | [15:8] Reserved for future use |
| 34 | Envelope PWM_min | [7:0] Reserved for future use |
| 35 | Envelope PWM_max | [15:8] Reserved for future use |
| 36 | Envelope PWM_max | [7:0] Reserved for future use |

Source Port

This will be set to the Source Port of the Host that initiated the Discovery Packet.

Destination Port

This will be set to 1024.

Sequence Number

A 4-byte integer set to 0x00000000.

Bytes 5 & 6

These two bytes form a 16 bit number that specifies the port that Receiver Specific commands will be sent to. If set to zero the default port 1025 will be used.

Bytes 7 & 8

These two bytes form a 16 bit number that specifies the port that Transmitter Specific commands will be sent to. If set to zero the default port 1026 will be used.

Bytes 9 & 10

These two bytes form a 16 bit number that specifies the port that High Priority commands will be sent to. If set to zero the default port 1027 will be used.

Bytes 11 & 12

These two bytes form a 16 bit number that specifies the port that High Priority commands from the hardware will be sent from. If set to zero the default port 1025 will be used.

Bytes 13 & 14

These two bytes form a 16 bit number that specifies the port that Receiver Audio will be sent to. If set to zero the default port 1028 will be used.

Bytes 15 & 16

These two bytes form a 16 bit number that specifies the port that transmitter I&Q data will be sent to. If set to zero the default port 1029 will be used.

Bytes 17 & 18

These two bytes form a 16 bit number that specifies the port that Receiver 0 I&Q data will originate from. If set to zero the default port 1035 will be used.. Each subsequent receiver will increment the port number respectively e.g. Receiver 1 will originate from Port + 1, Receiver 2 from Port +2.....Receiver 79 from Port + 79

Bytes 19 & 20

These two bytes form a 16 bit number that specifies the port that microphone or line in data will originate from. If set to zero the default port 1026 will be used.

Bytes 21& 22

These two bytes form a 16 bit number that specifies the port that wideband data from ADC0 will originate from. If set to zero the default port 1027 will be used.. Each subsequent wideband data will increment the port number respectively e.g. ADC1 1 will originate from Port + 1, ADC 2 from Port +2.....ADC7 from Port + 7

Byte 23

Enable wideband data. A set bit enables Wideband data from an associated ADC to be sent e.g. bit 0 enables ADC0, bit1 enables ADC1 etc.

Bytes 24 & 25

These two bytes form a 16 bit number that specifies the number of wideband samples to use per packet. The default is 512 by 16 bits samples. (default only at present)

Byte 26

Sets the size of a wideband sample in bits. If set to zero the default of 16 bits will be used. (default only at present)

Byte 27

Sets the update rate of the wideband data in mS.

Byte 28

Sets the number of packets of wideband data sent per frame. The default is 32 (i.e. for defaults will send 32 * 512 = 16k by 16 bit samples per frame). For ANAN-10E this is fixed at 1024 by 16 bit samples per frame.

Bytes 29 & 30

These two bytes form a 16 bit number that specifies the port that memory mapped data from the PC will be sent to. If set to zero the default port xxxx will be used.

Bytes 31 & 32

These two bytes form a 16 bit number that specifies the port that memory mapped data to the PC will be sent to. If set to zero the default port xxxx will be used.

Bytes 33 & 34

These two bytes form a 16 bit number that specifies the minimum pulse width for the Envelope Tracking PWM.

Bytes 35 & 36

These two bytes form a 16 bit number that specifies the maximum pulse width for the Envelope Tracking PWM.

Byte 37

Bits when set activate the following functions; Bit[0] – Enable time stamping of Receiver I&Q packets, Bit[1] - send data using VITA-49 format, Bit[2] – select VNA mode, Bit[3] selects if the receiver and transmitter frequency data is sent as frequency ([3] = 0) (in Hz) or phase word ([3] = 1). A phase word is calculated as follows:

$$\text{phase_word}[31:0] = 2^{32} * \text{frequency(Hz)} / \text{DSP clock frequency (Hz)}$$

DSP clock frequency is dependent on the Board type and is either specified in Appendix A or, if hardware specific, then as part of the Discovery response as specified in Appendix B.

NOTE: Currently ALL openHPSDR FGPA code requires transmit and receive phase words.

Byte 56

This selects the Atlas bus Mercury receiver configuration as follows:

| Configuration (Mercury) |
|-------------------------|
| 000 - single receiver |
| 001 - two receivers |
| 010 - three receivers |
| 011 - four receivers |

Byte 57

For Atlas based systems this selects the source of the 10MHz reference clock as follows:

| 10MHz reference source |
|-------------------------------------|
| 00 = 10MHz reference from Atlas bus |
| 01 = 10MHz reference from Penelope |
| 10 = 10MHz reference from Mercury |

Byte 58

Bit[0] when set enables the PA. When in VNA mode or when using the Transverter output, the PA stage may be disabled.

Bit[1] when set enables the Apollo automatic ATU if fitted.

For Atlas based systems, Bit[2] when set enables Mercury Common Frequency and Bit [3] selects the Clock Source - see below

| Clock Source |
|------------------------------------|
| 0 = 122.88MHz source from Penelope |
| 1 = 122.88MHz source from Mercury |

Byte 59

Each bit enables the respective Alex filter board e.g. Bit[0] set enables Alex0, Bit[1] set enables Alex 1 etc.

RECEIVER SPECIFIC PACKET

This sets the number of ADCs and the number of receivers associated with each ADC. It also sets receiver parameters that change infrequently. This packet is sent following a successful Discovery command and prior to a Run command or when a parameter changes and, optionally, periodically.

The format of the packet is as follows:

| Control Elements - PC to Hardware | | |
|-----------------------------------|------------------------|--------------------------------------|
| Byte | Rx Specific | Notes |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Number of ADCs | Max of 8 ADCs |
| 5 | Bits - Dither ADC0...7 | [0] = ADC0, [1] = ADC1....[7] = ADC7 |
| 6 | Bits - Random ADC0..7 | [0] = ADC0, [1] = ADC1....[7] = ADC7 |
| 7 | Rx Enable Rx0....Rx7 | [0] = Rx0, [1]= Rx1.....[7] = Rx7 |
| 8 | Rx Enable Rx8....Rx15 | |
| 9 | Rx Enable Rx16....Rx23 | |
| 10 | Rx Enable Rx24....Rx31 | |
| 11 | Rx Enable Rx32....Rx39 | |
| 12 | Rx Enable Rx40....Rx47 | |
| 13 | Rx Enable Rx48....Rx55 | |
| 14 | Rx Enable Rx56....Rx63 | |
| 15 | Rx Enable Rx64....Rx71 | |
| 16 | Rx Enable Rx72....Rx79 | [0] = Rx72.....[7] = Rx79 |
| 17 | ADC Rx0 | ADC(n) that Rx0 is allocated to |
| 18 | Sampling Rate Rx0 | [15:8] 48/96/192/384/768/1536 |
| 19 | Sampling Rate Rx0 | [7:0] |
| 20 | CIC1 Rx0 | For Future use |
| 21 | CIC2 Rx0 | For Future use |
| 22 | Sample Size Rx0 | Default 24 bits |
| 23 | ADC Rx1 | ADC(n) that Rx1 is allocated to. |
| 24 | Sampling Rate Rx1 | [15:8] |
| 25 | Sampling Rate Rx1 | [7:0] |
| 26 | CIC1 Rx1 | |
| 27 | CIC2 Rx1 | |
| 28 | Sample Size Rx1 | |
| 29 | ADC Rx2 | ADC(n) that Rx2 is allocated to. |
| 30 | Sampling Rate Rx2 | [15:8] |
| 31 | Sampling Rate Rx2 | [7:0] |
| 32 | CIC1 Rx2 | |

| | | |
|------|--------------------|---|
| 33 | CIC2 Rx2 | |
| 34 | Sample Size Rx2 | |
| 35 | ADC Rx3 | |
| 36 | Sampling Rate Rx3 | [15:8] |
| 37 | Sampling Rate Rx3 | [7:0] |
| 38 | CIC1 Rx3 | |
| 39 | CIC2 Rx3 | |
| 40 | Sample Size Rx3 | |
| 41 | ADC Rx4 | |
| 42 | Sampling Rate Rx4 | [15:8] |
| 43 | Sampling Rate Rx4 | [7:0] |
| 44 | CIC1 Rx4 | |
| 45 | CIC2 Rx4 | |
| 46 | Sample Size Rx4 | |
| ... | | |
| ... | | |
| 485 | ADC Rx78 | |
| 486 | Sampling Rate Rx78 | |
| 487 | Sampling Rate Rx78 | |
| 488 | CIC1 Rx78 | |
| 489 | CIC2 Rx78 | |
| 490 | Sample Size Rx78 | |
| 491 | ADC Rx79 | |
| 492 | Sampling Rate Rx79 | |
| 493 | Sampling Rate Rx79 | |
| 494 | CIC1 Rx79 | |
| 495 | CIC2 Rx79 | |
| 496 | Sample Size Rx79 | |
| ... | | |
| ... | | |
| 1363 | SyncRx0 | [7:0] If bit set then Rx(n) is synched or muxed to Rx0 |
| 1364 | SyncRx1 | [7:0] If bit set then Rx(n) is synched or muxed to Rx1 |
| 1365 | SyncRx2 | [7:0] If bit set then Rx(n) is synched or muxed to Rx2 |
| ... | | |
| 1442 | SyncRx79 | [7:0] If bit set then Rx(n) is synched or muxed to Rx79 |
| 1443 | Mux | [7:0] If bit set then Rx(n) is in Multiplexed mode |

Destination Port

This may be set using the General packet and if zero defaults to 1025.

Sequence Number

A 4-byte integer set to 0x00000000.

Byte 4

Indicates the number of ADC that the hardware supports. This will be up to four on Atlas based systems, one on Hermes (ANAN-10/10E/100) and two on Angelia and Orion (ANAN-100D/200D),

Byte 5

A set bit activates Dither on the associated ADC e.g. Bit[0] activates ADC0, Bit[1] activates ADC1 etc.

Byte 6

A set bit activates Random on the associated ADC e.g. Bit[0] activates ADC0, Bit[1] activates ADC1 etc.

Byte 7

A set bit enables the associated receiver e.g. Bit[0] activates Receiver 0, Bit[1] activates Receiver 1 etc.

Bytes 8 to 16

A set bit enables receivers 8 through 79.

Byte 17

Selects the ADC that Receiver 0 is connected to where 0 connects to ADC0, 1 to ADC1 etc.

Bytes 18 and 19

These two bytes form a 16 bit word that selects the sampling rate of Receiver 0. Valid rates are 48/96/192/384/768/1536 ksp/s.

Bytes 20 & 21

For future use – to enable selection of the decimation rates of Receiver 0 CIC filters.

Byte 22

Sets Receiver 0 I&Q data sample size – default is 24 bits.

Bytes 23 to 496

Sets the ADC, sampling rate, CIC rates and data sample size of receiver 1 to 79 as above.

Bytes 1363 to 1442

Sets the Receiver that Receiver (n) is synchronised or multiplexed with. If a bit is set then Rx(n) is synchronised or multiplexed to the associated receiver. See the description of synchronous and multiplexed receivers that follows.

Byte 1443

A set bit indicates that the receiver indicated by the set bit is multiplex with others. The receiver(s) to which it is multiplexed is indicated by set bits in the relevant Byte 497 to 1442.

Synchronous and Multiplexed Receivers

NOTE: The sampling rate of all Synchronous or Multiplexed receivers must be the same and is the responsibility of the PC Control program to ensure this.

Receivers that are connected to a base receiver, either Synchronised or Multiplexed, are usually disabled so they are not also sent from an Ethernet port. It is the responsibility of the PC Control program to ensure this.

The selection code will allow unsuitable or unnecessary receiver combinations e.g. Rx0 + Rx0 or Rx0 + Rx1 and Rx1 + Rx0. It is the responsibility of the PC Control program to prevent this.

There is no special provision for PureSignal operation. For PureSignal use, the PC Control program is responsible for setting the sampling rates, selecting DAC data as the source for one receiver and selecting either Synchronous or Multiplex operation of the RF and DAC receivers.

Synchronous Receivers: (where a number of receivers are phase synchronous)

The maximum number of synchronised receivers is equal to the number of ADCs.

For synchronous receivers, if SyncRx[n] is > 0 then Rx[n] is synchronised with another receiver(s). The bit(s) set indicate which receiver(s) are synchronised e.g. bit[0] = Rx0, bit[1] = Rx1.....bit[7] = Rx7.

All receivers' frequencies will be set to the frequency of the base receiver. If SyncRx[n] is = 0 then there are no synchronous receivers selected.

NOTE: For the time being, due to FPGA size limitations and timing closure issues only Rx0 and Rx1 may be synchronised with synchronised data presented from Rx0 DDC output.

Multiplexed Receivers: (where a number of receivers are multiplexed over the one Ethernet port and may or may not be at a common frequency)

The maximum number of Multiplexed receivers is equal to the number of receivers.

For multiplexed receivers if Mux(n) bit n is set then Rx(n) is multiplexed with another receiver(s). SyncRx[n] bits [7:0] when set indicate which receiver(s) are multiplexed together e.g. bit[0] = Rx0, bit[1] = Rx1.....bit[7] = Rx7.

NOTE: For the time being, due to FPGA size limitations and timing closure issues, only Rx0 and Rx1 may be multiplexed with multiplexed data presented from Rx0 DDC output.

TRANSMITTER SPECIFIC PACKET

This sets the number of DACs and transmitter parameters that change infrequently. This packet is sent following a successful Discovery command and prior to a Run command or when a parameter changes and, optionally, periodically.

The format of the packet is as follows:

| | Control Elements - PC to Hardware | |
|--------|--|-------------------------|
| Byte | Tx Specific | Notes |
| | | |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Number of DACs | Max of 4 |
| 5 | Bits - Mode, CW, Reverse, Key Mode | See Below |
| 6 | Sidetone Level | |
| 7 | Sidetone Frequency (Hz) | [15:8] |
| 8 | Sidetone Frequency (Hz) | [7:0] |
| 9 | Keyer Speed | |
| 10 | Keyer Weight | |
| 11 | Hang delay | [15:8] |
| 12 | Hang delay | [7:0] |
| 13 | RF Delay | |
| 14 | Tx0 Sampling Rate | [15:8] |
| 15 | Tx0 Sampling Rate | [7:0] |
| 16 | Tx0 Bits | |
| 17..25 | | Reserved for future use |
| 26 | Tx0 Phase Shift (0 - 359 degrees) | [15:8] |
| 27 | Tx0 Phase Shift | [7:0] |
| 28..33 | | Reserved for future use |
| ... | | |
| ... | | |
| 50 | Bits - line in, mic boost, Orion mic | See Below |
| 51 | Line in gain | |
| 52..58 | | Reserved for future use |
| 59 | Step Attenuator ADC0 on Tx0 (0 - 31dB) | Reserved for future use |

Destination Port

This may be set using the General packet and if zero defaults to 1026.

Sequence Number

A 4-byte integer set to 0x00000000.

Byte 4

Indicates the number of DACs the hardware supports. Presently unused.

Byte 5

If no bits are set then CW is not selected, otherwise indicates the selection of CW options as follows:

| | |
|--|----------------------------|
| Bits - Mode, CW, Reverse, Key Mode. 0 = off, 1 = on. | |
| [0] | EER |
| [1] | CW |
| [2] | Reverse CW Keys |
| [3] | Iambic |
| [4] | Sidetone |
| [5] | Mode B (Mode A if not set) |
| [6] | Strict Character Spacing |
| [7] | Break_in |

Byte 6

Sets the CW sidetone level, 0 = off, 255 = max

Bytes 7 & 8

Sets the CW sidetone frequency in Hz

Byte 9

Sets the CW keyer speed, 0 to 60 WPM

Byte 10

Sets the CW weight, 33 to 66, nominal is 50

Bytes 11 & 12

Sets the CW hang delay in mS

Byte 13

Sets the RF delay in mS

Bytes 14 & 15

Sets Tx0 sampling rate. For current hardware fixed at 192ksps.

Byte 16

Sets number of bits in the Tx I&Q data. For current hardware fixed at 24 bits per sample.

Bytes 17 to 49.

Reserved for future use.

Byte 50

Allows the selection of Line in or Microphone and Microphone selection for an Orion board (ANAN-200D) as follows:

| |
|--|
| Bits - line in, mic boost, Orion mic. 0 = off, 1 = on |
| [0] = Line in |
| [1] = Mic Boost |
| [2] = 0 = Orion mic PTT enabled, 1 = Orion mic PTT disabled |
| [3] = 0 = Orion mic PTT to ring and mic/mic bias to tip, 1 = Orion mic PTT to tip and mic/mic bias to ring |
| [4] = 0 = disables Orion mic bias, 1 = enables Orion microphone bias |

TRANSMITTER SYNCHRONISATION PACKET

The Transmitter Synchronisation packet is used to configure synchronous transmitters.

The data is sent prior to a Run command, whenever a value changes and, optionally, periodically.

For future use.

HIGH PRIORITY DATA PACKET

A High Priority Packet is sent to the associated SDR hardware whenever data changes and may also be sent periodically. It should be sent at a higher priority than any other packet. It should be sent after a successful Discovery process after configuration is complete. The format is as follows:

| Control Elements - PC to Hardware Port (Default 1027) | | |
|---|---------------------------|------------------------------------|
| Byte | High Priority | Notes |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Bits - run, PTT(n) | [0] = run, [1] = PTT0...[4] = PTT3 |
| 5 | CWX0 | [0] = CWX, [1] = Dot, [2] = Dash |
| 6 | CWX1 | Reserved for future use |
| 7 | CWX2 | Reserved for future use |
| 8 | CWX3 | Reserved for future use |
| 9 | Frequency/phase word Rx0 | [31:24] |
| 10 | | [23:16] |
| 11 | | [15:8] |
| 12 | | [7:0] |
| 13 | Frequency/phase word Rx1 | [31:24] |
| 14 | | [23:16] |
| 15 | | [15:8] |
| 16 | | [7:0] |
| 17 | Frequency/phase word Rx2 | [31:24] |
| 18 | | [23:16] |
| 19 | | [15:8] |
| 20 | | [7:0] |
| ... | | |
| ... | | |
| 325 | Frequency/phase word Rx79 | [31:24] |
| 326 | | [23:16] |
| 327 | | [15:8] |
| 328 | | [7:0] |
| 329 | Frequency/phase word Tx0 | [31:24] |
| 330 | Tx0 | [23:16] |
| 331 | Tx0 | [15:8] |
| 332 | Tx0 | [7:0] |
| 333 | Frequency/phase word Tx1 | Reserved for future use |
| 334 | Tx1 | Reserved for future use |
| 335 | Tx1 | Reserved for future use |

| | | |
|------|---------------------------|---|
| 336 | Tx1 | Reserved for future use |
| 337 | Frequency/phase word Tx2 | Reserved for future use |
| 338 | Tx2 | Reserved for future use |
| 339 | Tx2 | Reserved for future use |
| 340 | Tx2 | Reserved for future use |
| 341 | Frequency/phase word Tx3 | Reserved for future use |
| 342 | Tx3 | Reserved for future use |

| 1442 | Step Attenuator 1 (0 - 31dB) | |
| 1443 | Step Attenuator 0 (0 - 31dB) | |

Destination Address

This will be the Ethernet address assigned to the hardware.

Destination Port

This may be set using the General packet and if zero defaults to 1027.

Sequence Number

A 4-byte integer set to 0x00000000.

Byte 4

Bit [0] when set enables the associated SDR hardware and when clear disables. Bit [1] enables transmit of the associated SDR hardware. Bits [2] to [7] are reserved for future use.

Byte 5

Bit[0] when set selects CW mode from the Host (e.g. a CW keyboard) with bit[1] and[2] being dot and dash respectively. A set bit will send a dot or dash at the speed selected by the Tx Specific packet.

Bytes 9 to 12

These bytes represent a 32bit word that is used to set the frequency of Rx0 in Hz.

Bytes 13 to 16

These bytes represent a 32bit word that is used to set the frequency of Rx1 in Hz.

Bytes 17 to 328

These bytes represent a 32bit word that is used to set the frequency of Rx2 to Rx79.

Bytes 329 to 332

These bytes represent a 32bit word that is used to set the frequency of Tx0 in Hz.

Byte 345

This byte sets the power out from Tx0. 0 represents 0 power out and 255 maximum.

Byte 1417

A set bit enables the associated open collector output. [0] = OC0, [1] = OC2.....[6] = OC6.

Byte 1418

A set bit enables the associated Atlas Metis board User Outputs DB9 connector pins 1-4. [0] = pin1....[3] = pin4

Byte 1419

A set bit enables the 20dB attenuate on the associated Atlas Mercury board. [0] = Mercury1....[3] = Mercury4.

Bytes 1432 to 1435

These bytes form a 32bit word that selects the various functions on the (Alex) High and Low pass filters, preamplifier and antenna switching. See Appendix D for the mapping of bits to functions.

Byte 1442

Selects the attenuation applied to the 0-31dB attenuator before ADC1 (Angelia, Orion, ANAN-100D, ANAN-200D only).

Byte 1443

Selects the attenuation applied to the 0-31dB attenuator before ADC0 (not Mercury boards).

RECEIVER AUDIO PACKET

The Receiver Audio packet contains left and right audio to be presented to the hardware audio DAC.

It is sent whenever 360 Left and Right audio samples are available. Data defaults to 16 bits per sample at 48ksps.

| | Rx Audio Data (default port 1028) | |
|------|-----------------------------------|---------|
| Byte | Data | Notes |
| | | |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Left Audio Sample 0 | [15:8] |
| 5 | Left Audio Sample 0 | [7:0] |
| 6 | Right Audio Sample 0 | [15:8] |
| 7 | Right Audio Sample 0 | [7:0] |
| 8 | Left Audio Sample 1 | [15:8] |
| 9 | Left Audio Sample 1 | [7:0] |
| 10 | Right Audio Sample 1 | [15:8] |
| 11 | Right Audio Sample 1 | [7:0] |
| | | |
| | | |
| 1440 | Left Audio Sample 358 | [15:8] |
| 1441 | Left Audio Sample 358 | [7:0] |
| 1442 | Right Audio Sample 359 | [15:8] |
| 1443 | Right Audio Sample 359 | [7:0] |

Destination Port

This may be set using the General packet and if zero defaults to 1028.

Sequence Number

A 4-byte unsigned integer representing a sequence of packets from this port. The sequence starts at 0x00000000 and rolls over after exceeding 0xFFFFFFFF.

Each port decoder keeps a separate sequence count such that the hardware can determine if a decoder is missing samples in its stream. The sequence number is set to zero at program start or whenever a stop command is sent.

Bytes 4 to 144

A sequence of 360 2-byte signed integer 2's Complement values representing demodulated samples for the audio DAC on the hardware. These are sequential in time from the first to last sample.

TRANSMITTER I&Q DATA PACKET

The I & Q data packet contains data to be presented to the hardware DUC(n). It is sent whenever 480 I&Q samples are available. Default samples are 24 bits at 192ksps.

| | Tx I&Q Data (default port 1029) | |
|-------------|--|--------------|
| Byte | Data | Notes |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | I Sample 0 | [23:16] |
| 5 | I Sample 0 | [15:8] |
| 6 | I Sample 0 | [7:0] |
| 7 | Q Sample 0 | [23:16] |
| 8 | Q Sample 0 | [15:8] |
| 9 | Q Sample 0 | [7:0] |
| 10 | I Sample 1 (or Envelope data) | [23:16] |
| 11 | I Sample 1 (or Envelope data) | [15:8] |
| 12 | I Sample 1 (or Envelope data) | [7:0] |
| 13 | Q Sample 1 (or Envelope data) | [23:16] |
| 14 | Q Sample 1 (or Envelope data) | [15:8] |
| 15 | Q Sample 1 (or Envelope data) | [7:0] |
| ... | | |
| ... | | |
| 1441 | Q Sample 479 | [23:16] |
| 1442 | Q Sample 479 | [15:8] |
| 1443 | Q Sample 479 | [7:0] |

Destination Port

This may be set using the General packet and if zero defaults to 1029 for DAC0. It is automatically incremented by one for each subsequent DAC.

Sequence Number

A 4-byte unsigned integer representing a sequence of packets from this port. The sequence starts at 0x00000000 and rolls over after exceeding 0xFFFFFFFF.

Each port decoder keeps a separate sequence count such that the hardware can determine if a decoder is missing samples in its stream. The sequence number is set to zero at program start or whenever a stop command is sent.

I/Q Sample

A sequence of 480 2-byte signed integer 2's Complement I & Q values representing samples for the DUC on the SDR hardware. These are sequential in time from the first to last sample.

NOTE: When Envelope Tracking (ET) or Envelope Elimination & Restoration (EER) mode is selected then alternative I&Q pairs are for Transmitter and Envelope use respectively.

MEMORY MAPPED REGISTERS FROM PC

The memory mapped registers from PC packet contains address and data to be sent to the hardware. The format is as follows:

| Memory Mapped - PC to hardware (default port xxxx) | | |
|--|---------------|---------|
| Byte | Memory Mapped | Notes |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Address0 | [15:8] |
| 5 | Address0 | [7:0] |
| 6 | Data0 | [31:24] |
| 7 | Data0 | [23:16] |
| 8 | Data0 | [15:8] |
| 9 | Data0 | [7:0] |
| 10 | Address1 | [15:8] |
| 11 | Address1 | [7:0] |
| 12 | Data1 | [31:24] |
| 13 | Data1 | [23:16] |
| 14 | Data1 | [15:8] |
| 15 | Data1 | [7:0] |
| 16 | Address2 | [15:8] |
| 17 | Address2 | [7:0] |
| 18 | Data2 | [31:24] |
| 19 | Data2 | [23:16] |
| 20 | Data2 | [15:8] |
| 21 | Data2 | [7:0] |
| 22 | Address3 | [15:8] |
| 23 | Address3 | [7:0] |

| 1443 | Data239 | [7:0] |

Destination Port

This may be set using the General packet and if zero defaults to xxxx.

Sequence Number

A 4-byte unsigned integer representing a sequence of packets from this port. The sequence starts at 0x00000000 and rolls over after exceeding 0xFFFFFFFF.

Each port decoder keeps a separate sequence count such that the hardware can determine if a decoder is missing samples in its stream. The sequence number is set to zero at program start or whenever a stop command is sent.

Bytes 4 & 5 (en sequence)

These form the 16 bit address the 32 bit data in the next 4 bytes will be sent to.

Bytes 6 to 9 (en sequence)

This form a 32 bit data word that will be sent to the address specified by the address bytes.

openHPSDR Hardware to Host Protocol

The hardware will communicate with the Host using standard UDP protocol. Byte order shall be MSB first (little Endian) and all values are interpreted as unsigned integers unless otherwise noted.

IP and UDP headers are as per UDP/IP standards.

Key:

| |
|---------------------------|
| IP Header (24 bytes) |
| UDP Header (8 bytes) |
| UDP Data (variable bytes) |

| <div>Bits</div> <div>Bytes</div> | 0-7 | 8-15 | 16-23 | 24-31 | 32- 39 | 40-47 | 48-55 | 56-63 |
|----------------------------------|------------------------|-----------------|------------------|-------|-------------------|-------|-----------------------|-------|
| 0 | Version/IHL | Type of Service | Total Length | | Identification | | Flags/Fragment Offset | |
| 8 | TTL | Protocol | Header Checksum | | Source IP Address | | | |
| 16 | Destination IP Address | | | | IP Options | | | Pad |
| 24 | Source Port | | Destination Port | | UDP Length | | UDP Checksum | |
| 32... 1443 | UDP Data | | | | | | | |

Future diagrams will only show the UDP Data with a starting byte reference of zero.

DISCOVERY REPLY PACKET

A Discovery Reply Packet is sent in response to a Host broadcasting a Discovery packet. The Host sends a discovery packet in order to determine what hardware is present on the network and how it is configured.

In order to allow for SDR hardware to provide complete details of all features available two reply formats are provided.

1. Where prior knowledge of the hardware is known by the Host software, and
2. Where the full description of the configuration of the hardware and its capabilities are provided in the response to the Discovery packet.

The data format for option 1 is shown below.

| Response to Discovery - Hardware to Host (from port 1024) | | |
|--|--------------------------------------|-------------------------|
| Byte | To IP address and Port of Host PC | Notes |
| | | |
| 0 | Seq # = 0 | [31:24] |
| 1 | Seq # = 0 | [23:16] |
| 2 | Seq # = 0 | [15:8] |
| 3 | Seq # = 0 | [7:0] |
| 4 | 0x02 (or 0x03) | Response to Discovery |
| 5 | Board MAC | MSB |

| 20 | Number of receivers implemented | |
| 21 | Frequency or phase word | 0 = frequency 1 = phase |
| 22 | | |
| 23 | | |
| 24 | | |
| 25 | | |
| | | |
| 59 | | |

Source Port

This will be set to 1024.

Destination Port

This will be set to the Source Port of the Host that initiated the Command.

Sequence Number

A 4-byte integer set to 0x00000000.

Byte 4

Normally 0x02 but if the hardware is running and already connected to a different Host it will be 0x03.

If byte 4 is 0xFF then subsequent bytes contain the hardware configuration of the SDR. Appendix A describes the format of the hardware configuration.

MAC

This is 6 bytes and holds the MAC address of the hardware that is responding to the Command request

Board Type

A byte interpreted as follows:

| |
|--|
| 0: board = "ATLAS" |
| 1: board = "HERMES" (ANAN-10,100) |
| 2: board = "HERMES" (ANAN-10E, 100E) |
| 3: board = "ANGELA" (ANAN-100D) |
| 4: board = "ORION" (ANAN-200D) |
| 5: Reserved |
| 6: board = "Hermes Lite" |
| 7: Reserved |
| 8: Reserved |
| 9: Reserved |
| 254: XML hardware description follows |
| 255: Full hardware description follows |

Hardware descriptions for Board types less than 254 are documented in Appendix A. For a Board type of 254 a full hardware description is returned in XML format, see Appendix B. For a Board type of 255 a full hardware description is returned, see Appendix C.

Byte 12 - Code Version

A byte that indicates the version of this protocol that the board(s) implement. The Host interprets this as a decimal number e.g. 104 would be interpreted as version 10.4

Byte 13 - Code Version

For non-Atlas based systems, a byte that indicates the version of code loaded into the associated board. The Host interprets this as a decimal number e.g. 104 would be interpreted as version 10.4.

Bytes 14 to 19

Where an Atlas based system is identified, bytes 13 to 18 contain the code versions loaded into the respective boards. . The Host interprets this as a decimal number e.g. 104 would be interpreted as version 10.4. A version number of zero indicates a board is not present.

Byte 20

This holds the number of independent receivers that is implemented in the hardware.

Byte 21

This indicates if the hardware requires frequencies to be send as a frequency (Hz) or a phase word. A phase word is calculated as follows:

$$\text{phase_word}[31:0] = 2^{32} * \text{frequency(Hz)} / \text{DSP clock frequency (Hz)}$$

COMMAND REPLY PACKET

A Command reply packet is returned to the Host making the Command request. The format of the reply is the same as a Discovery reply, up to and including byte 18, except that byte 4 (and for Program the sequence number) is different.

The reply is returned in response to the following:

Erase. Following an EEPROM erase command the hardware will respond with a reply packet that indicates the command has been received and, after the erase is complete – which may take 10's of seconds, that the erase has been successful. Byte 4 will be set to 0x03.

Program. Following a Program command the hardware will respond with a reply packet that indicates that the next 256 bytes of data should be sent by the Host. Byte 4 will be set to 0x04 and the sequence number will be set to the last sequence number received from the Host.

During programming the Host should check the received sequence number in order to verify that a programming packet has been received and in the correct sequence. An incorrect sequence number should be used by the Host to initiate a new Erase and Program cycle.

Set IP. Following a successful Set IP command the hardware will respond with a Discovery reply packet.

HIGH PRIORITY STATUS PACKET

The High Priority Status packet contains data that indicates the status of the transceiver subsystems. This data is sent when the data changes and, optionally, periodically.

Any change of Status data will be sent as a priority and has precedence over any other packet.

Since actual status changes will be hardware specific the format will vary between different SDR hardware.

The packet format is as follows:

| Control Elements - Hardware to PC (default port 1025) | | |
|---|------------------------|--|
| Byte | High Priority | Notes |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Bits - PTT, Dot, Dash | [0] = PTT, [1] = Dot, [2] = Dash, [4] PLL locked |
| 5 | Bits - ADC Overload | [0] = ADC0...[7] = ADC7 |
| 6 | Exciter Power 0 | [15:8] |
| 7 | Exciter Power 0 | [7:0] |
| 8 | Exciter Power 1 | [15:8] Reserved for future use |
| 9 | Exciter Power 1 | [7:0] Reserved for future use |
| 10 | Exciter Power 2 | [15:8] Reserved for future use |
| 11 | Exciter Power 2 | [7:0] Reserved for future use |

| ... | | |
| 48 | 0 | Presently unused |
| 49 | Supply Volts | [15:8] |
| 50 | Supply Volts | [7:0] |
| 51 | User ADC3 | [15:8] |
| 52 | User ADC3 | [7:0] |
| 53 | User ADC2 | [15:8] |
| 54 | User ADC2 | [7:0] |
| 55 | User ADC1 | [15:8] |
| 56 | User ADC1 | [7:0] |
| 57 | User ADC0 | [15:8] |
| 58 | User ADC0 | [7:0] |
| 59 | Bits - User logic inputs | [0] = IO0....[7] = IO7 |

Source Port

This may be set using the General packet and if zero defaults to 1025.

Destination Port

This will be set to the Source Port of the Host that initiated the Discovery Packet.

Sequence Number

A 4-byte integer set to 0x00000000. The sequence starts at 0x00000000 and rolls over after exceeding 0xFFFFFFFF. Each port decoder keeps a separate sequence count such that the Host can determine if a decoder is missing samples in its stream. The sequence number is set to zero at power on or whenever a stop command is received.

Byte 4

Bits [0] to [2] indicate the status of an attached PTT button or CW key. A bit is set when the input is active. Bit [4] set indicates that the PLL that locks the master VCXO to the 10MHz internal or external reference is locked.

Byte 5

Bits [0] to [7] are set if the associated ADC[n] overload bit is set.

Bytes 6 & 7

These form a 16 bit word that represents the forward power from the exciter (or Penelope or Penny Lane boards). The conversion to power (mW) is to multiply the word by ????

Bytes 14 & 15

These form a 16 bit word that represents the forward power from the exciter Power Amplifier. The conversion to power (Watts) is to multiply the word by 0.0168.

Bytes 22 & 23

These form a 16 bit word that represents the reverse power from the exciter Power Amplifier. The conversion to power (Watts) is to multiply the word by 0.0168.

Bytes 49 & 50

These form a 16 bit word that represents the supply voltage applied to the hardware (not Atlas bus systems).

The conversion to Volts is to multiply the word by 0.00525.

Bytes 51 to 58

These form 16 bit words that represent the general purpose analogue voltage inputs to the hardware. These are presently undefined since they are user specific.

Byte 59

Bits [0] to [7] are set if the associated general purpose digital input is set. These are presently undefined since they are user specific.

MICROPHONE DATA PACKET

The microphone data packet contains 720 samples from the microphone or line-in inputs on the hardware.

The sample rate is 48kps and packet format is as follows:

| | Microphone Data (default port 1026) | |
|------|-------------------------------------|---------|
| Byte | Data | Notes |
| | | |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Mic Sample 0 | [15:8] |
| 5 | Mic Sample 0 | [7:0] |
| 6 | Mic Sample 1 | [15:8] |
| 7 | Mic Sample 1 | [7:0] |
| 8 | Mic Sample 2 | [15:8] |
| 9 | Mic Sample 2 | [7:0] |
| 10 | Mic Sample 3 | [15:8] |
| 11 | Mic Sample 4 | [7:0] |
| | | |
| | | |
| 1440 | Mic Sample 718 | [15:8] |
| 1441 | Mic Sample 718 | [7:0] |
| 1442 | Mic Sample 719 | [15:8] |
| 1443 | Mic Sample 719 | [7:0] |

Source Port

This may be set using the General packet and if zero defaults to 1026.

Destination Port

This will be set to the Source Port of the Host that initiated the Discovery Packet.

Sequence Number

A 4-byte unsigned integer representing a sequence of packets from this port. The sequence starts at 0x00000000 and rolls over after exceeding 0xFFFFFFFF.

Each port decoder keeps a separate sequence count such that the Host can determine if a decoder is missing samples in its stream. The sequence number is set to zero at power on or whenever a stop command is received.

Mic Sample

A sequence of 720 2-byte signed integer 2's Complement values representing samples from the microphone or line-in on the hardware. These are sequential in time from the first to last sample.

WIDEBAND DATA PACKET

The Wideband data packet contains raw samples from the ADCs selected by the user. The number of bits per sample, number of samples per packet and update rate specified in the General to Hardware settings will be sent when the Wideband enable bit for the associated ADC is set.

The following assumes 512 by 16 bit samples per packet.

| Wideband Data (default port 1027) | | |
|-----------------------------------|---------------------|---------|
| Byte | Data | Notes |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Wideband Sample 0 | [15:8] |
| 5 | Wideband Sample 0 | [7:0] |
| 6 | Wideband Sample 1 | [15:8] |
| 7 | Wideband Sample 1 | [7:0] |
| 8 | Wideband Sample 2 | [15:8] |
| 9 | Wideband Sample 2 | [7:0] |
| 10 | Wideband Sample 3 | [15:8] |
| 11 | Wideband Sample 3 | [7:0] |
| | | |
| | | |
| 1024 | Wideband Sample 510 | [15:8] |
| 1025 | Wideband Sample 510 | [7:0] |
| 1026 | Wideband Sample 511 | [15:8] |
| 1027 | Wideband Sample 511 | [7:0] |

Source Port

This may be set using the General packet and if zero defaults to 1027 for ADC0. The source port is automatically incremented by one for each subsequent Wideband data source.

Destination Port

This will be set to the Source Port of the Host that initiated the Discovery Packet.

Sequence Number

A 4-byte unsigned integer representing a sequence of packets from this port. The sequence starts at 0x00000000 and rolls over after exceeding 0xFFFFFFFF.

Each port decoder keeps a separate sequence count such that the Host can determine if a decoder is missing samples in its stream. The sequence number is set to zero at power on or whenever a block of raw samples has been sent or whenever a stop command is received.

ADC Sample

A sequence of 2-byte signed integer values (default is 512) representing raw samples from the selected ADC

on the hardware. These are sequential in time from the first to last sample. Following a request to send wideband data, the sequence number will be set to zero and incremented in each sequential packet until the number of samples set in the General packet has been sent. The sequence number is reset to zero for the next packet or when a stop command is received.

RECEIVER PACKET

I & Q data from a DDC connected to an ADC will be sent from a UDP port with bits per sample specified by the General settings. I & Q data from either a single receiver or multiple synchronous or multiplexed receivers can be presented.

The following assumes one receiver using 24 bits per sample.

| Receiver I&Q Data (Rx0 default port 1035) | | |
|--|-----------------------|---------|
| Byte | Data | Notes |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Time Stamp | [63:56] |
| 5 | Time Stamp | [55:48] |
| 6 | Time Stamp | [47:40] |
| 7 | Time Stamp | [39:32] |
| 8 | Time Stamp | [31:24] |
| 9 | Time Stamp | [23:16] |
| 10 | Time Stamp | [15:8] |
| 11 | Time Stamp | [7:0] |
| 12 | Bits per sample | [15:8] |
| 13 | Bits per sample | [7:0] |
| 14 | I&Q Samples per frame | [15:8] |
| 15 | I&Q Samples per frame | [7:0] |
| 16 | I Sample 0 | [23:16] |
| 17 | I Sample 0 | [15:8] |
| 18 | I Sample 0 | [7:0] |
| 19 | Q Sample 0 | [23:16] |
| 20 | Q Sample 0 | [15:8] |
| 21 | Q Sample 0 | [7:0] |
| 22 | I Sample 1 | [23:16] |
| 23 | I Sample 1 | [15:8] |
| 24 | I Sample 1 | [7:0] |
| 25 | Q Sample 1 | [23:16] |
| 26 | Q Sample 1 | [15:8] |
| 27 | Q Sample 1 | [7:0] |
| ... | | |
| ... | | |
| 1441 | Q Sample 238 | [23:16] |
| 1442 | Q Sample 238 | [15:8] |
| 1443 | Q Sample 238 | [7:0] |

Source Port

The receiver port will be as allocated by the General Packet and if zero defaults to 1035 for Receiver 0. Each additional receiver will be allocated the next sequential port number e.g. Receiver 1 will originate from port 1036.

Destination Port

This will be set to the Source Port of the Host that initiated the Discovery Command

Sequence Number

A 4-byte unsigned integer representing a sequence of packets from this port. The sequence starts at 0x00000000 and rolls over after exceeding 0xFFFFFFFF.

Each port decoder keeps a separate sequence count such that the Host can determine if a decoder is missing samples in its stream. The sequence number is set to zero at power on or whenever a stop command is received.

Time stamp

This is a 64 bit unsigned integer that is incremented at the sample rate of the ADC from which the data is being generated and is set to zero at the 0 to 1 transition of the 1 PPS from a GPS receiver. This complies with the 'Fractional -Seconds Timestamp - The Sample Count Timestamp' of the VITA-49 specification section 6.1.5.1.

Bits per sample

A two byte unsigned integer that indicates the number of bits per sample. Current hardware FPGA code supports 24 bits per sample.

I&Q Samples per frame

A two byte unsigned integer that indicates the number of samples that follow. The number of samples will not exceed the maximum length of the data payload for a UDP packet and will contain an integer number of I&Q samples. Where synchronous or multiplexed receiver data is presented then the UDP packet will contain an integer number of samples e.g. for two synchronous receivers [(I0, Q0), (I1, Q1)] x 164.

The data diagram above illustrates the case for one receiver. Should a greater number of synchronous or multiplexed receivers be used the above data format will be modified accordingly. The number of samples per UDP frame will depend on the width of each I & Q sample i.e. 8, 16, 24, or 32 bits.

Receiver I/Q Samples

This is a sequence of signed integer 2's Complement values representing one I or one Q sample from the receiver hardware. These are sequential in time from the first to last sample.

For synchronous or multiplexed receivers the sample rate of each receiver will be the same and specified by the register settings set using the Receiver Specific packet.

MEMORY MAPPED REGISTERS FROM HARDWARE

The memory mapped registers from PC packet contains address and data to be sent to the PC. The data should be sent whenever data changes and optionally periodically. The format is as follows:

| Memory Mapped - Hardware to PC (default port xxxx) | | |
|--|---------------|---------|
| Byte | Memory Mapped | Notes |
| 0 | Seq # | [31:24] |
| 1 | Seq # | [23:16] |
| 2 | Seq # | [15:8] |
| 3 | Seq # | [7:0] |
| 4 | Address0 | [15:8] |
| 5 | Address0 | [7:0] |
| 6 | Data0 | [31:24] |
| 7 | Data0 | [23:16] |
| 8 | Data0 | [15:8] |
| 9 | Data0 | [7:0] |
| 10 | Address1 | [15:8] |
| 11 | Address1 | [7:0] |
| 12 | Data1 | [31:24] |
| 13 | Data1 | [23:16] |
| 14 | Data1 | [15:8] |
| 15 | Data1 | [7:0] |
| 16 | Address2 | [15:8] |
| 17 | Address2 | [7:0] |
| 18 | Data2 | [31:24] |
| 19 | Data2 | [23:16] |
| 20 | Data2 | [15:8] |
| 21 | Data2 | [7:0] |
| 22 | Address3 | [15:8] |
| 23 | Address3 | [7:0] |
| 24 | Data3 | [31:24] |
| 25 | Data3 | [23:16] |
| 26 | Data3 | [15:8] |
| 27 | Data3 | [7:0] |
| ... | | |
| 1438 | Address239 | [15:8] |
| 1439 | Address239 | [7:0] |
| 1440 | Data239 | [31:24] |
| 1441 | Data239 | [23:16] |
| 1442 | Data239 | [15:8] |
| 1443 | Data239 | [7:0] |

Destination Port

This may be set using the General packet and if zero defaults to xxxx.

Sequence Number

A 4-byte unsigned integer representing a sequence of packets from this port. The sequence starts at 0x00000000 and rolls over after exceeding 0xFFFFFFFF.

Each port decoder keeps a separate sequence count such that the hardware can determine if a decoder is missing samples in its stream. The sequence number is set to zero at program start or whenever a stop command is sent.

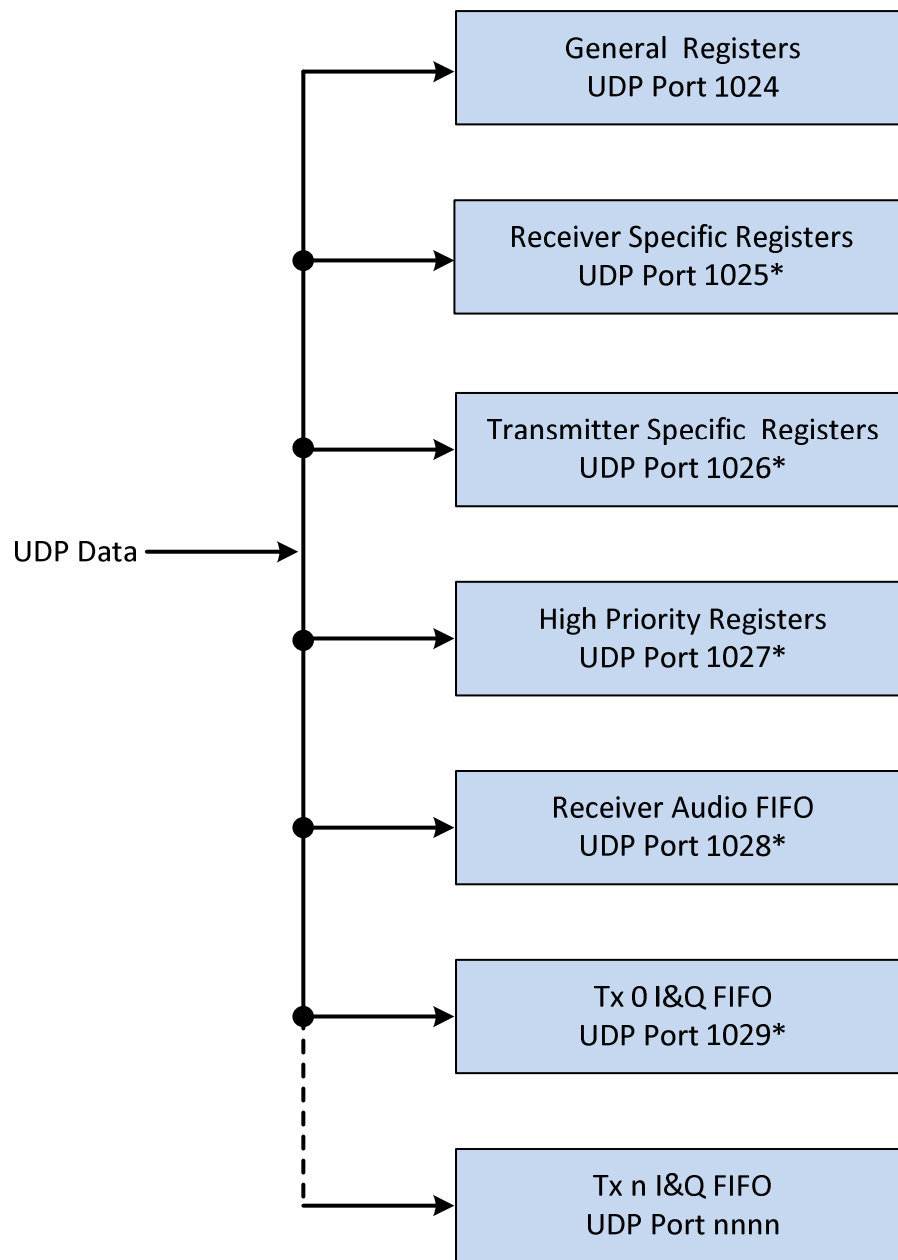

Bytes 4 & 5 (en sequence)

These form the 16 bit address the 32 bit data in the next 4 bytes will be sent from.

Bytes 6 to 9 (en sequence)

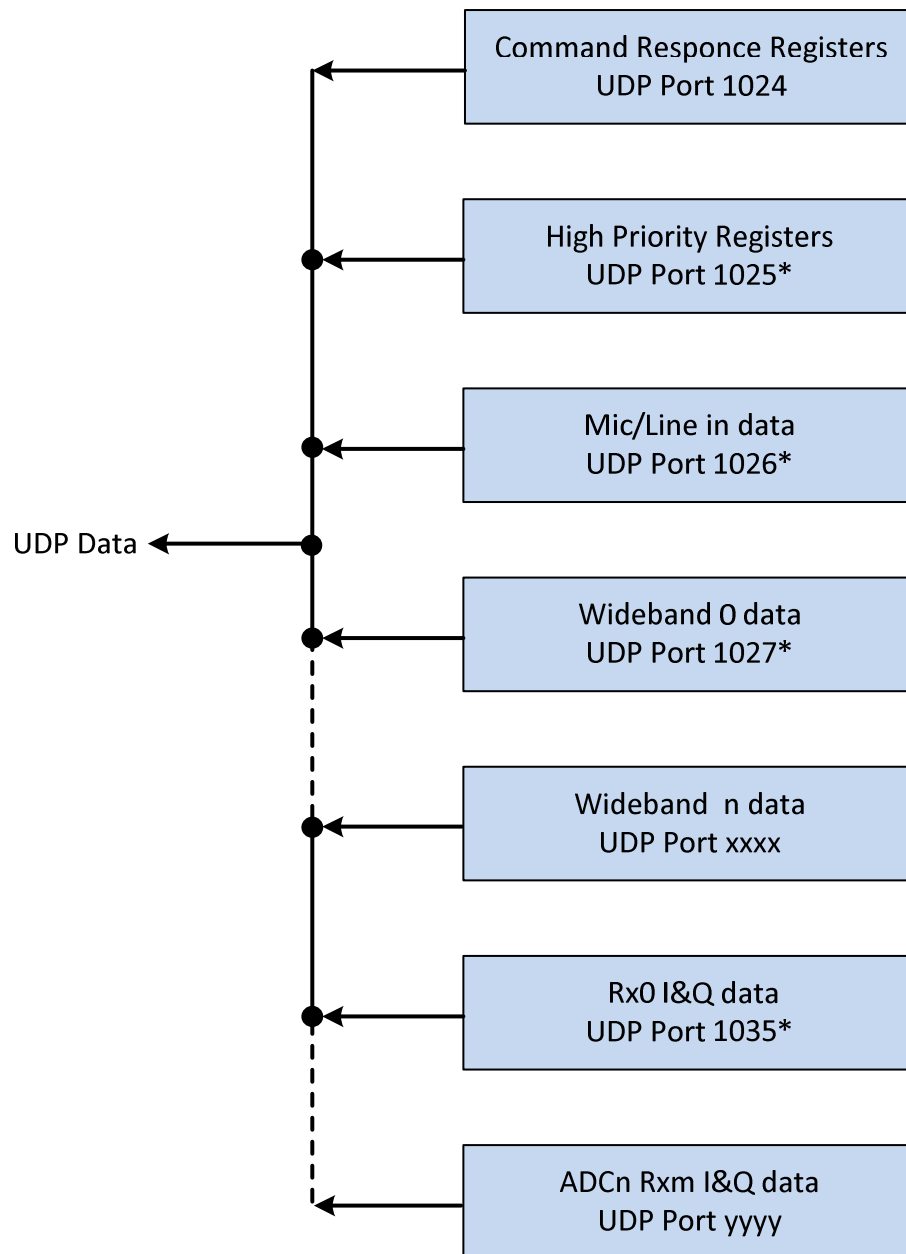

This form a 32 bit data word that is the data contained at the address specified by the address bytes.

Appendix A – Hardware capabilities – openHPSDR boards

Board 0 = Atlas Based Systems

To be written

Board 1 = Hermes (ANAN-10, 100)

| Hardware Capabilities | |
|--|-----------|
| Host update of firmware supported | Yes |
| Setting of UDP/IP ports supported | Yes |
| Setting IP address supported | Yes |
| Memory mapped registers supported | No |
| Alex protocol receive filters supported | Yes |
| Alex protocol transmit filters supported | Yes |
| VITA-49 protocol supported | No |
| DSP clock frequency (Hz) | 122.88MHz |
| Number of RF ADCs | 1 |
| Dither supported | Yes |
| Random supported | Yes |
| Number of receivers supported | TBA |
| Receiver Frequency or Phase Word | Phase |
| Receive attenuator supported | Yes |
| Wideband data supported | Yes |
| Wideband samples per Ethernet packet | 512 |
| Wideband bits per sample fixed or variable | Fixed |

| | |
|--|----------------------|
| Wideband bits per sample fixed value | 16 |
| Wideband update rate fixed or variable | Variable |
| Wideband update rate fixed (mS) | |
| Wideband packets per frame fixed or variable | Variable |
| Wideband packets per frame fixed | |
| Individual receiver sample rates supported | Yes |
| Minimum Rx sampling rate (ksps) | 48 |
| Maximum Rx sampling rate (ksps) | 1,536 |
| CIC decimation values settable | No |
| Synchronous receivers supported | No |
| Multiplexed receivers supported | Yes (for PureSignal) |
| Rx Audio CODEC supported | Yes, stereo |
| Audio CODEC sample rate (ksps) | 48 |
| Audio CODEC bits per sample | 16 |
| Audio samples per Ethernet packet | 720 |
| Time stamping of I&Q data supported | No |
| Number of transmitters supported | 1 |
| Tx Audio CODEC supported | Yes |
| Microphone supported | Yes |

| | |
|--|------------------------------|
| Line in supported | Yes |
| Audio CODEC sample rate (ksps) | 48 |
| Audio CODEC bits per sample | 16 |
| Audio samples per Ethernet packet | 720 |
| Transmitter Frequency or phase word required | Phase |
| Transmitter I&Q sample rate (ksps) | 192 |
| Bits per I/Q sample | 24 |
| I&Q samples per Ethernet packet | 480 I samples, 480 Q samples |
| Envelope Tracking supported | No |
| CW Sidetone supported | Yes |
| CW from the Host supported | Yes |
| CW Iambic Keyer supported | Yes |
| CW break-in supported | Yes |
| Hang supported (mS) | Yes, 1000 |
| RF Delay supported (mS) | Yes, 255 |
| Tx Phase shift supported | No |
| Receive attenuator on Tx supported | Yes |
| Open collector outputs supported | 7 |
| Receiver Calibration | -138dBm (see Note) |
| | |

| | |
|--|---|
| Number of General Purpose ADCs | 6 |
| Calibration constant for Supply Voltage. $V = \text{ADC value} / 4095 * \text{constant}$ | constant = 3.3 |
| Calibration constant for Exciter, FWD & REV power $W = (\text{ADC value} / 4095 * \text{constant1})^2 / \text{constant2}$ Sale Exciter to 0 to 1000mW Scale ANAN-10 FWD & REV 0 to 20W Scale ANAN-100 FWD & REV 0 – 150W | Constant1 = 3.3 Constant2 = 0.09 (ANAN-10) Constant2 = 0.095 (ANAN-100) |

NOTE: Receiver calibration. Calibration level is with a 50 ohm load connected to the antenna input, the receiver set to 20m, 500 Hz bandwidth and is the averaged value of the magnitude of the I&Q samples at the output of the filter i.e. receiver noise floor.

Board 2 = Hermes (ANAN-10E)

| Hardware Capabilities | |
|--|---|
| Host update of firmware supported | No, use Bootloader mode |
| Setting of UDP/IP ports supported | No, use Bootloader mode |
| Setting IP address supported | No, use Bootloader mode |
| Memory mapped registers supported | No |
| Alex protocol receive filters supported | No |
| Alex protocol transmit filters supported | Yes (only used on Tx output) |
| VITA-49 protocol supported | No |
| DSP clock frequency (Hz) | 122,880,000 |
| Number of ADCs | 1 |
| Dither supported | Yes |
| Random supported | Yes |
| Number of receivers supported | 2 |
| Receiver Frequency or Phase Word | Phase |
| Receive attenuator supported | Yes, 0 to 31dB only, no Alex attenuators. |
| Wideband data supported | Yes |
| Wideband samples per Ethernet packet | 512 |
| Wideband bits per sample fixed or variable | Fixed |

| | |
|--|----------------------|
| Wideband bits per sample fixed value | 16 |
| Wideband update rate fixed or variable | Fixed |
| Wideband update rate fixed (mS) | 100 |
| Wideband packets per frame fixed or variable | Fixed |
| Wideband packets per frame fixed | 4 |
| Individual receiver sample rates supported | Yes |
| Minimum Rx sampling rate (ksps) | 48 |
| Maximum Rx sampling rate (ksps) | 1,536 |
| CIC decimation values settable | No |
| Synchronous receivers supported | No |
| Multiplexed receivers supported | Yes (for PureSignal) |
| Rx Audio CODEC supported | Yes, stereo |
| Audio CODEC sample rate (ksps) | 48 |
| Audio CODEC bits per sample | 16 |
| Audio samples per Ethernet packet | 360 left, 360 Right |
| Time stamping of I&Q data supported | No |
| Number of transmitters supported | 1 |
| Tx Audio CODEC supported | Yes |
| Microphone supported | Yes |

| | |
|--|---------------------|
| Line in supported | Yes |
| Audio CODEC sample rate (ksps) | 48 |
| Audio CODEC bits per sample | 16 |
| Audio samples per Ethernet packet | 720 |
| Transmitter Frequency or phase word required | Phase |
| Transmitter I&Q sample rate (ksps) | 192 |
| Bits per I/Q sample | 24 |
| Tx I&Q samples per Ethernet packet | 480 I, 480 Q |
| Envelope Tracking supported | No |
| CW Sidetone supported | Yes |
| CW from the Host supported | Yes |
| CW Iambic Keyer supported | Yes |
| CW break-in supported | Yes |
| Hang supported (mS) | Yes, 1000 |
| RF Delay supported (mS) | Yes, 255 |
| Tx Phase shift supported | No |
| Receive attenuator on Tx supported | Yes |
| Open collector outputs supported | 7 |
| Receiver Calibration | -138dBm (see Note) |

| | |
|--|-------------------------------------|
| Number of General Purpose ADCs | 6 |
| Calibration constant for Supply Voltage. $V = \text{ADC value} / 4095 * \text{constant}$ | constant = 3.3 |
| Calibration constant for Exciter, FWD & REV power $W = (\text{ADC value} / 4095 * \text{constant1})^2 / \text{constant2}$ Sale Exciter to 0 to 1000mW Scale ANAN-10E FWD & REV 0 to 20W | Constant1 = 3.3 Constant2 = 0.09 |

NOTE: Receiver calibration. Calibration level is with a 50 ohm load connected to the antenna input, the receiver set to 20m, 500 Hz bandwidth and is the averaged value of the magnitude of the I&Q samples at the output of the filter i.e. receiver noise floor.

Board 3 = Angelia (ANAN-100D)

| Hardware Capabilities | |
|--|-------------|
| Host update of firmware supported | Yes |
| Setting of UDP/IP ports supported | Yes |
| Setting IP address supported | Yes |
| Memory mapped registers supported | No |
| Alex protocol receive filters supported | Yes |

Source Port

This will be set to 1024.

Destination Port

This will be set to the Source Port of the Host that initiated the Command.

Sequence Number

A 4-byte integer set to 0x00000000.

Byte 4

Normally 0x02 but if the hardware is running and already connected to a different Host it will be 0x03.

Bytes 5 to 10 - MAC

This is 6 bytes and holds the MAC address of the hardware that is responding to the Command request

Byte 12

A byte that indicates the openHPSDR Protocol Version supported. The Host interprets this as a decimal number e.g. 104 would be interpreted as version 10.4.

Byte 13 - Firmware Code Version

A byte that indicates the version of code loaded into the associated board(s). The Host interprets this as a decimal number e.g. 15 would be interpreted as version 1.5.

Bytes 14 to 19

Where an Atlas based system is identified, bytes 14 to 19 contain the code versions loaded into the respective boards. A version number of zero indicates a board is not present.

Byte 20

Bit[0] set when openHPSDRProgrammer.exe can be used to update the FPGA code.

Byte 21

Bit[0] set when other than default UDP/IP ports can be set.

Byte 22

Bit[0] set when openHPSDRProgrammer.exe can be used to set a fixed IP address.

Byte 23

Bit[0] set when memory mapped registers supported

Byte 24

Bit[0] set when Alex protocol receive filters supported

Byte 25

Bit[0] set when Alex protocol transmit filters supported

Byte 26

Bit[0] set when VITA-49 protocol supported

Bytes 27 to 30

A four byte value representing the DSP clock frequency in Hz

Byte 36

A byte indicating the number of ADC available

Byte 37

Bit[0] set indicates that ADC dither is supported

Byte 38

Bit[0] set indicates that ADC random is supported

Byte 39

A byte indicating the number of receivers supported

Byte 40

Bit[0] set when phase words are required, if not set then frequency required.

Byte 41

Bit[0] set when receiver input attenuator supported

Byte 42

Bit[0] set when wideband (i.e. raw ADC samples) supported

Bytes 43 and 44

A 16 bit word indicating the number of wideband samples per Ethernet packet

Byte 45

Bit[0] set when variable bits per wideband sample are supported

Byte 46

A byte indicating the number of fixed bits per wideband sample

Byte 47

Bit[0] set when the wideband update rate is variable

Byte 48

A byte indicating the fixed wideband update rate

Byte 49

Bit[0] set when the number of wideband packets per frame are variable

Byte 50

A byte indicating the fixed number of wideband packets per frame

Byte 51

Bit[0] set when individual receiver sample rates are supported

Bytes 52 and 53

A 16 bit word indicating the minimum receiver sampling rate

Bytes 54 and 55

A 16 bit word indicating the maximum receiver sampling rate

Byte 56

Bit[0] set when CIC decimation values settable

Byte 57

A byte indicating the number of synchronous receivers supported, zero equates to none.

Byte 58

A byte indicating the number of multiplexed receivers supported, zero equates to none.

Byte 59

A byte indicating an Audio CODEC is supported, zero equates to no, 1 equates to mono and 2 to stereo

Byte 60

A byte indicating the Audio CODECs sampling rate in ksps

Byte 61

A byte indicating the Audio CODEC bits per sample

Byte 62 and 63

A 16 bit word indicating the number of audio samples per Ethernet packet

Byte 64

Bit[0] set when time stamping of I&Q samples is supported

Byte 70

A byte indicating the number of transmitters supported, zero equates to none

Byte 71

Bit[0] set when a transmitter Audio CODEC is supported

Byte 72

Bit[0] set when a microphone input to the transmitter Audio CODEC is supported

Byte 73

Bit[0] set when a line input to the transmitter Audio CODEC is supported

Byte 74

A byte indicating the Audio CODEC's sampling rate in ksps

Byte 75

A byte indicating the Audio CODEC bits per sample

Byte 76 and 77

A 16 bit word indicating the number of audio samples per Ethernet packet

Byte 78

Bit[0] set when a transmitter phase word is required, if zero then frequency required

Byte 79

A byte indicating the transmit I&Q data sample rate in ksps

Byte 80

A byte indicating the transmit I&Q data sample size in bits

Byte 81 and 82

A 16 bit word indicating the number transmitter I&Q samples per Ethernet packet

Byte 83

Bit[0] set when an Envelope Tracking or Envelope Elimination and Restoration amplifier is supported

Byte 84

Bit[0] set when hardware CW sidetone generation is supported

Byte 85

Bit[0] set when CW from host is supported

Byte 86

Bit[0] set when an Iambic hardware CW keyer is supported

Byte 87

Bit[0] set when CW break-in is supported

Bytes 89 and 89

A 16 bit word indicating the maximum delay of CW Hang supported in mS. A zero value indicates not supported

Byte 90

A byte indicating the maximum delay of RF Delay supported in mS. A zero value indicates not supported

Byte 91

Bit[0] set indicates transmitter RF phase shift supported

Byte 92

Bit[0] set indicates the receiver front end attenuator may be activated on transmit is supported. A zero value indicates not supported

Byte 93

A byte indicating the number of open collector outputs supported. A zero value indicates none.

Bytes 94 and 95

A 16 bit word indicating the calibration value for a receiver. The value is the maximum value of an I or Q sample with a RF input of -20dBm at a frequency of 14.200 MHz with the receiver tuned to 14.210 MHz and the sample rate set a 48ksps. This value is intended to enable a bandscope and/or S Meter to be calibrated.

Byte 96

A byte indicating the number of general purpose ADCs available. These are typically used to indicate forward and reverse powers, supply voltages and temperatures etc.

Appendix D – Alex filters description

High Pass Filters (HPF) and Low Pass Filters (LPF) may be used with any openHPSDR board set.

The filters are called 'Alex' filters (short for Alexiares) which were initially designed by Graham, KE9H, for use with the original Atlas based hardware. The original Alex filters are currently used with Atlas based hardware but the design has evolved over time for use with other openHPSDR designs.

The method of controlling the various relays that select filters, 6m pre-amp, antennas and attenuators has not changed significantly over time. In which case this document will refer to Alex filters which implies the Alex data protocol rather than the original Alex hardware.

Whilst individual Alex implementations will differ, hence the specific descriptions that follow, the common factor is the use of a 32 bit data word [31:0] that controls the various filters, 6m pre-amp, antenna selection and attenuators.

The top 16 bits [31:16] control LPFs, antenna selection and the antenna change over relay whilst the lower 16 bits [15:0] control HPFs, receiver inputs and attenuators. In general a set bit activates a relay that selects a filter, antenna or attenuator.

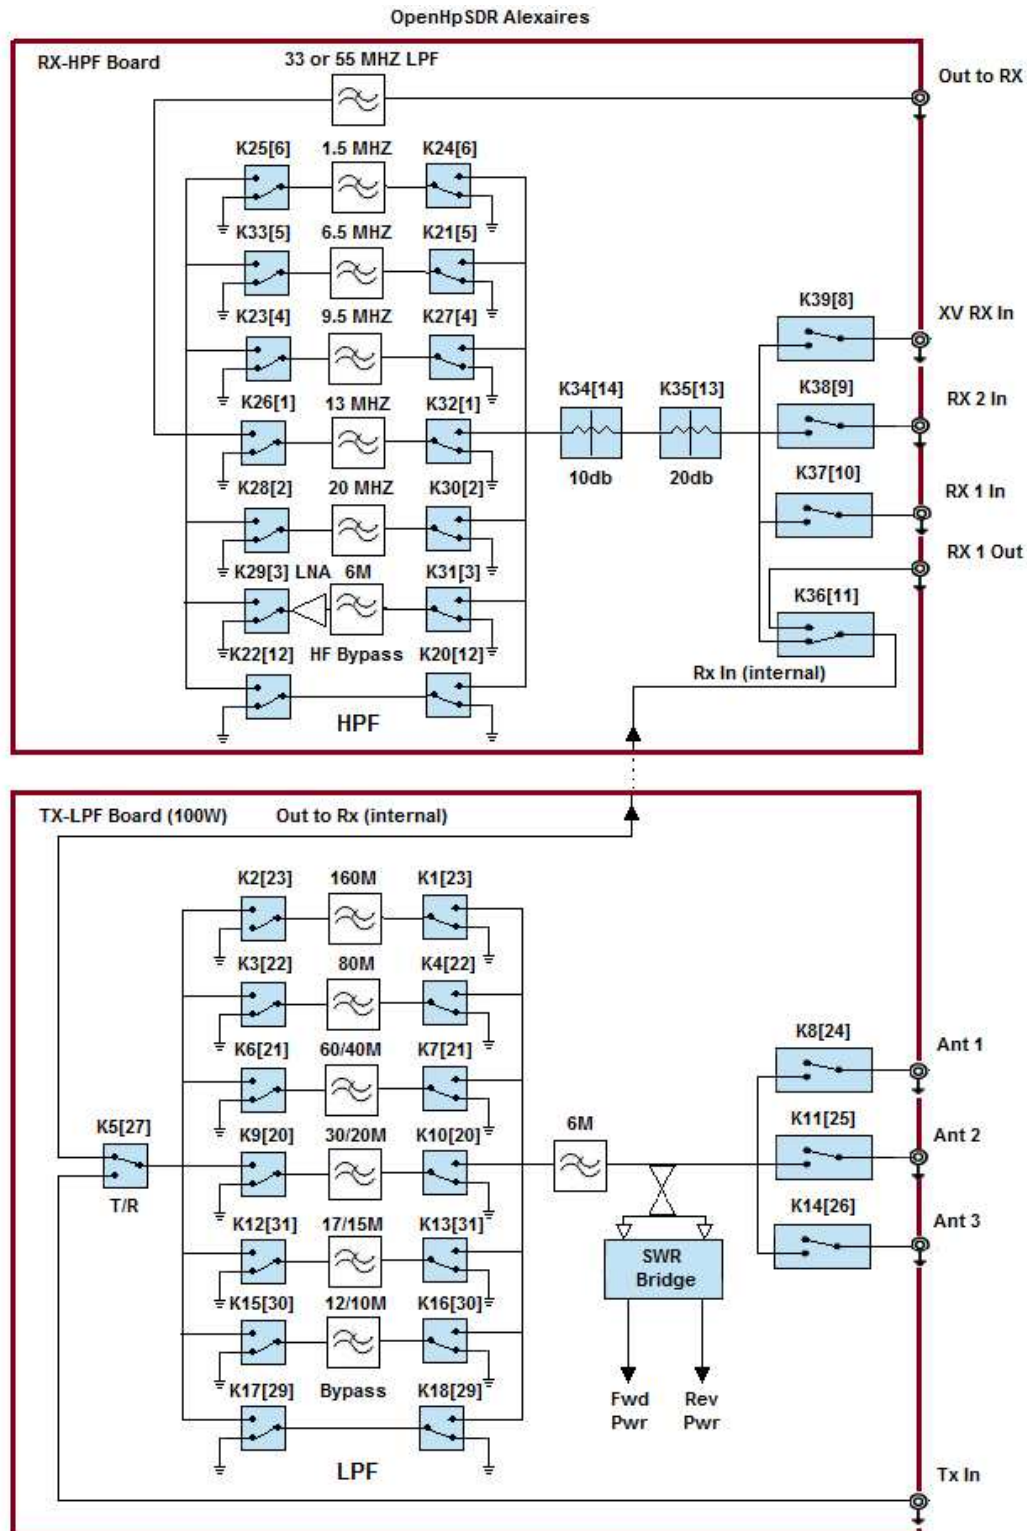

At power on all 32 bits are set to 0 by the FPGA code and remain in that state until an Alex command is received.

In the following block diagrams the numbers against each relay refer to the relay designation in the relevant board schematic followed by the bit that operates it e.g. K2[23] indicates relay K2 which is operated when bit [23] is set.

Note that in order to use an Alex filter it is necessary to set the relevant bit in Byte 59 of the 'General to hardware' packet. Since all existing openHPSDR hardware includes only one Alex filter set, this will mean setting bit [0] of Byte 59.

ALEX FILTERS FOR ATLAS BASED SYSTEMS

The Alex filters used with Atlas based system comprise two circuit boards, one containing LPFs, Antenna selection and change over relay and the other HPFs, 6m pre-amp, Receive Antenna selection and Attenuators. A block diagram of the filter system is shown in the following diagram.

Relays are shown in de-energised state. The bits in the Alex data register map as follows:

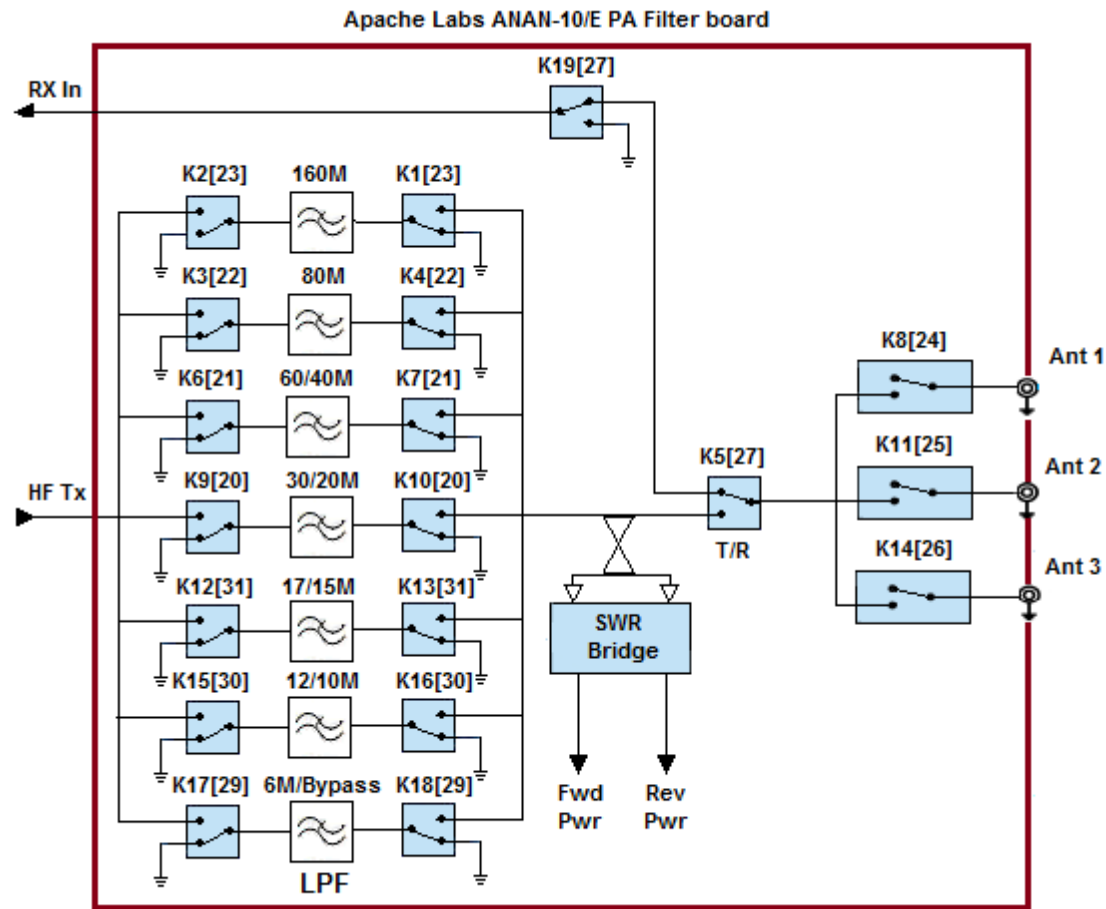

| Bit | Function | Bit | Function |
|-----|--------------|-----|------------------|
| 0 | YELLOW LED | 16 | N.C. |
| 1 | 13 MHz HPF | 17 | N.C. |
| 2 | 20 MHz HPF | 18 | N.C. |
| 3 | 6M Preamp | 19 | YELLOW LED |
| 4 | 9.5 MHz HPF | 20 | 30/20 Meters LPF |
| 5 | 6.5 MHz HPF | 21 | 60/40 Meters LPF |
| 6 | 1.5 MHz HPF | 22 | 80 Meters LPF |
| 7 | N.C. | 23 | 160 Meters LPF |
| 8 | XVTR RX In | 24 | ANT 1 |
| 9 | RX 2 In | 25 | ANT 2 |
| 10 | RX 1 In | 26 | ANT 3 |
| 11 | RX 1 Out | 27 | T/R |
| 12 | HF Bypass | 28 | RED LED |
| 13 | 20 dB Atten. | 29 | Bypass |
| 14 | 10 dB Atten. | 30 | 12/10 Meters LPF |
| 15 | RED LED | 31 | 17/15 Meters LPF |

Where all bits are active high and bit 27 high selects transmit.

More details of the board features can be found here: <http://openhpsdr.org/alex.php>

ALEX FILTERS FOR ANAN-10 & ANAN-10E SYSTEMS

Both these systems use LPFs only. A block diagram of the filter system is shown in the following diagram.

Copyright © 2015 William Diaz KC9XG

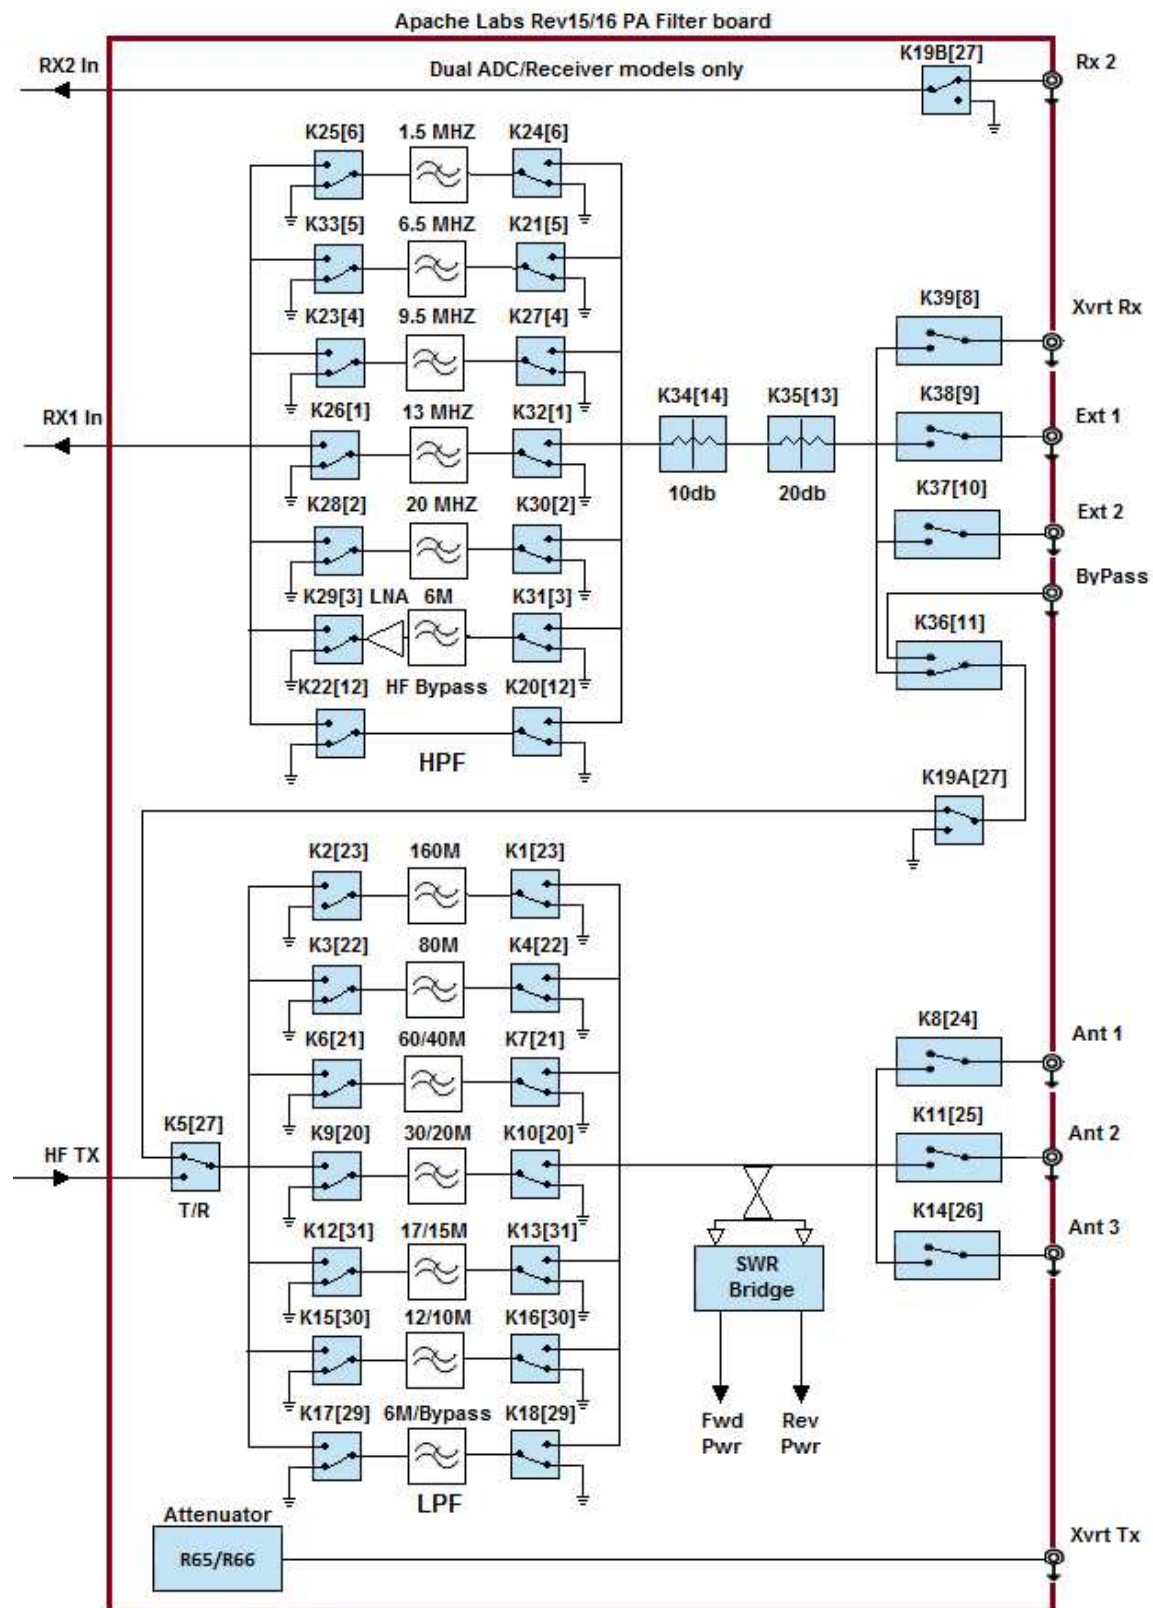

Relays are shown in de-energised state. The bits in the Alex data register map as follows:

| Bit | Function |
|-----|------------------|
| 20 | 30/20 Meters LPF |
| 21 | 60/40 Meters LPF |
| 22 | 80 Meters LPF |
| 23 | 160 Meters LPF |
| 24 | ANT 1 |
| 25 | ANT 2 |
| 26 | ANT 3 |
| 27 | T/R |
| 28 | N.C. |
| 29 | 6 Mtrs/Bypass |
| 30 | 12/10 Meters LPF |
| 31 | 17/15 Meters LPF |

Where all bits are active high and bit 27 high selects transmit.

ALEX FILTERS FOR ANAN-100, 100D AND 200D SYSTEMS (REV 15/16)

The following block diagram relates to Rev15/16 boards which were fitted prior to **February 2015**.

| 4 | 9.5 MHz HPF | 20 | 30/20 Meters LPF |
| 5 | 6.5 MHz HPF | 21 | 60/40 Meters LPF |
| 6 | 1.5 MHz HPF | 22 | 80 Meters LPF |
| 7 | N.C. | 23 | 160 Meters LPF |
| 8 | Xvrt Rx | 24 | ANT 1 |
| 9 | Ext 1 | 25 | ANT 2 |
| 10 | Ext 2 | 26 | ANT 3 |
| 11 | ByPass | 27 | T/R |
| 12 | HF Bypass | 28 | RED LED |
| 13 | 20 dB Atten. | 29 | 6M/Bypass |
| 14 | 10 dB Atten. | 30 | 12/10 Meters LPF |
| 15 | RED LED | 31 | 17/15 Meters LPF |

Where all bits are active high and bit 27 high selects transmit.

ALEX FILTERS FOR ANAN- 100/100B/100E/200D SYSTEMS (REV 24)

The following block diagram relates to Rev24 boards which were fitted post **February 2015**.

Copyright © 2015 William Diaz KC9XG

Relays are shown in de-energised state. The bits in the Alex data register map as follows:

| Bit | Function | Bit | Function |
|-----|--------------|-----|------------------|
| 0 | YELLOW LED | 16 | N.C. |
| 1 | 13 MHz HPF | 17 | N.C. |
| 2 | 20 MHz HPF | 18 | N.C. |
| 3 | 6M Preamp | 19 | YELLOW LED |
| 4 | 9.5 MHz HPF | 20 | 30/20 Meters LPF |
| 5 | 6.5 MHz HPF | 21 | 60/40 Meters LPF |
| 6 | 1.5 MHz HPF | 22 | 80 Meters LPF |
| 7 | N.C. | 23 | 160 Meters LPF |
| 8 | Xvrt Rx | 24 | ANT 1 |
| 9 | Ext 1 | 25 | ANT 2 |
| 10 | Ext 2 | 26 | ANT 3 |
| 11 | Bypass | 27 | T/R |
| 12 | HF Bypass | 28 | RED LED |
| 13 | 20 dB Atten. | 29 | 6M/Bypass |
| 14 | 10 dB Atten. | 30 | 12/10 Meters LPF |
| 15 | RED LED | 31 | 17/15 Meters LPF |

Where all bits are active high and bit 27 high selects transmit.
